Allison Young and Anna Berman 10/24/2018

Data Overview

In the 1970s, researchers in the United States ran several randomized experiments intended to evaluate public policy programs. One of the most famous experiments is the National Supported Work Demonstration (NSWD), in which researchers wanted to assess whether or not job training for disadvantaged workers had an effect on their wages. Eligible workers were randomly assigned either to receive job training or not to receive job training. Since this is a randomized experiment, we can make causal claims about the effect of job training on wages for this population of workers.

We analyze a subset of the data from the NSWD. These and other data were originally analyzed in a highly influential paper by the economist Robert Lalonde. The reference for the study is Lalonde, R. J. (1986), Evaluating the econometric evaluations of training programs with experimental data, The American Economic Review, 76, 604 - 620.

We will use linear and logistic regression modeling to answer the following questions of interest.

- Is there evidence that workers who receive job training tend to earn higher wages than workers who do not receive job training? What is a likely range for the effect of training? Is there any evidence that the effects differ by demographic groups? Are there other interesting associations with wages that are worth mentioning?
- Is there evidence that workers who receive job training tend to be more likely to have positive (non-zero) wages than workers who do not receive job training? What is a likely range for the effect of training? Is there any evidence that the effects differ by demographic groups? Are there other interesting associations with positive wages that are worth mentioning?

A summary of the dataset used in both our linear and logisitic regessions is summarized below:

Linear Regression

Exploratory Data Analysis

For concern of multicollinearity, we cannot include both nodegree and education in our model (nodegree is, in essence, a binned version of education with 0 being over 12 years of education and 1 being less than 12 years of education). We were originally concerned with including both 1974 salary (re74) and 1975 salary (re75), however, the correlation between these two variables is only 0.55 which low enough to allow both salary variables as predictors in our model. No other variables had high enough correlation to be a multicollinearity concern.

A plot of each predictor in relation to our outcome variable, 1978 salary is below.

Model Selection

Through a series of modeling fittings, we examined a variety of logistic models to answer the question, 'Is there evidence that workers who receive job training tend to earn higher wages than workers who do not receive job training?'. We evaluated each model based on R-squared value and whether addition variables and interactions resulted in a significant or near-significant nested F test results.

We attempted logging our outcome variable (1978 salary (re78)), logging 1974 and 1975 salaries, using nodegree as opposed to education, using education as a continuous variable as well as a binned factor variable. We also looked at potential interaction effects between treatment and education, treatment and black, treatment and hispanic, and treatment and age (see appendix Fig. 1 for plots of potential interaction effects). Additionally, we used mean-centered continuous variables to aid in interpretation.

Before we finalized our model selection we examined the residuals and influential points. The residuals of this model are normally distributed and have constant variance therefore fitting our assumptions of linear regression (see appendix). The most influential points in our model were determined to be corner cases and did not call for alteration of our final model. (For further details on our model's redisuals and influential

points, see appendix).

Ultimately, we selected the model summarized below.

Interpretation

Our model has an R-squared of 0.15. In other words, our model explains 15% of the variance 1978 salary.

Intercept: For non-black, non-hispanic, un-married individuals of average age, average 1974 and 1975 salaries, with High School only education, who did not recieve treatment, we estimate the average salary in 1978 to be \$6655.81 (95% CI: \$5233.7, \$8077.92).

Treatment: Holding all else constant, individuals who participated in the treatment are estimated to have average 1978 salaries increased by \$1612.92 (95% CI: \$81.26, \$3144.58).

Age: Holding all else constant, for each 10 years an individual ages on average we estimate his salary to increase by \$69.46 (95% CI: \$-567.56, \$706.47). Given that this confidence interval includes 0, we are not confident that there is a meaningful effect of age on 1978 salary.

Education: Holding all else contant, for an individual with:

- Less than a middle school education: we estimate avergage 1978 salary to be \$1693.62 less (95% CI: \$-3351.73, \$-35.51).
- Some high school education: we estimate avergage 1978 salary to be \$29.64 more (95% CI: \$-1397.94, \$1457.22). Given that this confidence interval includes 0, we are not confident that there is a meaningful effect of some high school compared to completion of high school on 1978 salary.

• More than a high school education: we estimate avergage 1978 salary to be \$2254.69 more (95% CI: \$283.68, \$4225.7).

Married: Holding all else constant, for married individuals we estimate average 1978 salaries to be \$518.65 more (95% CI: \$-849.41, \$1886.71). Given that this confidence interval includes 0, we are not confident that there is a meaningful effect of blackness on 1978 salary.

Black: Holding all else constant, for black individuals we estimate average 1978 salaries to be \$1278.32 less (95% CI: \$-2785.51, \$228.87). Given that this confidence interval includes 0, we are not confident that there is a meaningful effect of blackness on 1978 salary.

Hispanic: Holding all else constant, for black individuals we estimate average 1978 salaries to be \$357.44 more (95% CI: \$-1472.35, \$2187.24). Given that this confidence interval includes 0, we are not confident that there is a meaningful effect of hispanic ethnicity on 1978 salary.

1974 Salary: Holding all else constant, for each \$1,000 an individual made in 1974, on average we estimate his 1978 salary to be \$304.35 higher (95% CI: \$190.43, \$418.26).

1975 Salary: Holding all else constant, for each \$1,000 an individual made in 1975, on average we estimate his 1978 salary to be \$220.53 higher (95% CI: \$15.59, \$425.47).

Discussion

Because this is a randomized control trial, we can say treatment may result in increased salaries. However the effect size of treatment may be small.

- The effect is confounded by age, ethnicity, education, marital status, and previous salary.
- Both being black being hispanic, and being married may not have an effect on salary
- 1974 is more representative of earning potential in 1978 compared to 1975
- Unclear whether there is a huge difference between some hs and hs completion. Matters when you have less than ms or more than hs

Limitations

Our model has an R-squared of 0.15. In other words, our model explains 15% of the variance 1978 salary. It seems that we are missing variables in our model that would explain additional variation in 1978 salary, therefore more research is needed to fully understand the relationship between job training programs and salary and the mediating variables in this relationship.

Doesn't work for wealthy or older individuals (Why older?) Also black Outliers

Logistic Regression

Exploratory Data Analysis

In terms of mulicollinearity, the same reasoning from our linear regression applies to our logistic regression. Therefore our only restriction is a choice between either education or nodegree.

A plot of each predictor in relation to our outcome variable, employment in 1978 is below (employment being defined as salary above 0).

Table 1: Average employed '78 Cases by predictor

	0	1
treat	0.77	0.76
educ.bin2	0.79	0.67
black	0.80	0.72
hispan	0.76	0.83
married	0.76	0.78
nodegree	0.78	0.76

Model Selection

Through a series of modeling fittings, we examined a variety of linear models to answer the question, 'Is there evidence that workers who receive job training tend to be more likely to have positive (non-zero) wages than workers who do not receive job training?'. We evaluated each model based on the area under the curve (AUC) and whether addition variables and interactions resulted in a significant or near-significant change in deviance tests.

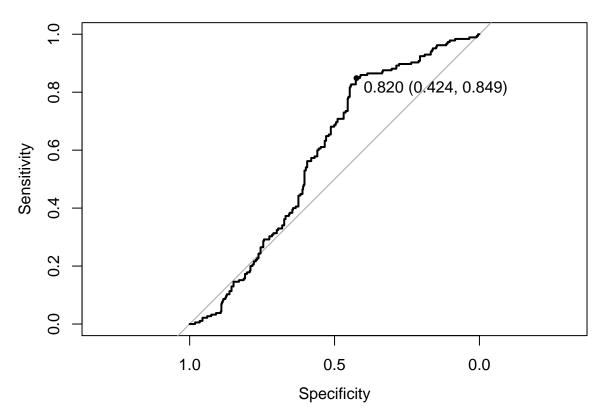

We attempted binning education in multiple ways, nonzero 1974 and 1975 variables. We also examoined potential interactions between treatment and previous salaries as well as interactions between treatment and level of education (see appendix for examination of interaction effects). Additionally, we used mean-centered continuous variables to aid in interpretation.

Before we finalized our model selection we examined the residuals and influential points. The residuals of this model are normally distributed and fit our assumptions of logistic regression (see appendix).

The most influential points in our model were determined to be corner cases and did not call for alteration of our final model. (For further details on our model's redisuals and influential points, see appendix).

Ultimately, we selected the model summarized below.

Interpretation

Our model has an AUC of 0.59. Using the suggested threshold of 0.82, our model has a sensitivity of 0.391 and a specificity of 0.175. In other words, our model correctly predicts 39.1% of nonzero wage earners and 82.5% of zero wage earners.

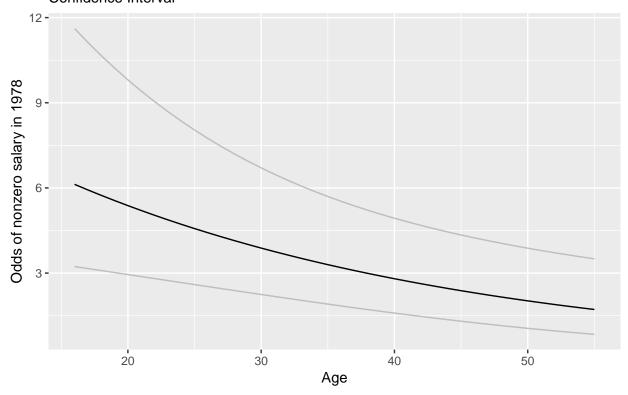

Intercept: For non-black, non-hispanic, un-married individuals of average age, average 1975 salaries and a zero 1974 salary, with some High School or more education, who did not recieve treatment, we estimate the odds of nonzero salary 1978 to be \$3.24 (95% CI: \$1.895, \$5.69).

Treatment: Holding all else constant, for individuals who participated in the treatment we estimate the odds of nonzero wage in 1978 to increase by a factor of 2.17 (95% CI: 1.15, 4.12).

Education: Holding all else contant, for an individual less than a middle school education we estimate e estimate the odds of nonzero wage in 1978 to decrease by a factor of 0.57 less (95% CI: 0.36, 0.9).

Age: Holding all else constant, for each 10 years an individual ages on average we estimate his salary to decrease by 0.72 (95% CI: 0.59, 0.89).

Odds of nonzero salary in 1978 by Age Confidence Interval

Married: Holding all else constant, for married individuals we estimate the odds of nonzero wage in 1978 to increase by a factor of 1.05 more (95% CI: \$0.65, 1.69). Given that this confidence interval includes 1, we are not confident that there is a meaningful effect of being married on odds of nonzero salary in 1978.

Black: Holding all else constant, for black individuals we estimate estimate the odds of nonzero wage in 1978 to decrease by a factor of 0.59 less (95% CI: \$0.35, 1).

Hispanic: Holding all else constant, for black individuals we estimate estimate the odds of nonzero wage in 1978 to increase by a factor of 1.23 more (95% CI: 0.63, 2.59). Given that this confidence interval includes 1, we are not confident that there is a meaningful effect of hispanic ethnicity on odds of nonzero salary in 1978.

1975 Salary: Holding all else constant, for each \$1,000 an individual made in 1975, on average we estimate estimate the odds of nonzero wage in 1978 to increase by a factor of 1.14 higher (95% CI:1.05, \$1.25).

Odds of nonzero salary in 1978 by 1975 Salary Confidence Interval

1974 Salary:

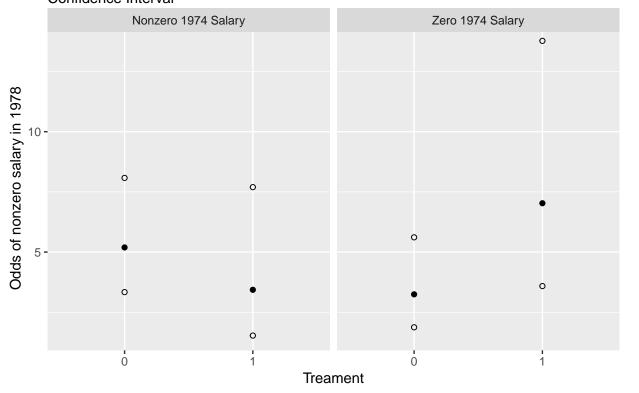

Waiting for profiling to be done...

*Zero Salary: Holding all else constant, for individuals who participated in the treatment we estimate the odds of nonzero wage in 1978 to increase by a factor of 2.17 (95% CI: 1.15, 4.12).

*Nonzero Salary: Holding all else constant, for individuals who participated in the treatment we estimate the odds of nonzero wage in 1978 to decrease by a factor of 0.74 (95% CI: 0.34, 1.67). Given that this confidence interval includes 1, we are not confident that there is a meaningful effect of treatment on nonzero salary in 1978 for those with nonzero salaries in 1974.

The influential points show that our model is not as accurate in its predictions for those who have high salaries in either 1974 or 1975. Because these are not the typical demographic to partake in a job training program, they are not of great interest for this research paper. Therefore we do not alter our model.
